

CS 443
Evaluation of Relational
Operations
Chapter 14

Slides adapted from Ramakrishnan & Gerhke pages.cs.wisc.edu/~dbbook/

Renée J. Miller

### Relational Operations

☐ We will consider how to implement:

- $\boxdot$  Selects a subset of rows from relation.
- $\Box$  <u>Projection</u> ( $\pi$ ) Deletes unwanted columns from relation.
- $\Box$  <u>Join</u> (  $\bowtie$  ) Allows us to combine two relations.
- □ <u>Set-difference</u> ( ) Tuples in reln. I, but not in reln. 2.
- $\Box$  <u>Union</u> ( $\bigcup$ ) Tuples in reln. I and in reln. 2.
- ☐ Aggregation (SUM, MIN, etc.) and GROUP BY
- ☐ Since each op returns a relation, ops can be *composed*! After we cover the operations, we will discuss how to *optimize* queries formed by composing them.

11/16/1

# Schema for Examples

Sailors (<u>sid:</u> integer, sname: string, rating: integer, age: real) Reserves (<u>sid:</u> integer, bid: integer, day: dates, rname: string)

- □ Similar to old schema; rname added for variations.
- □ Reserves:

3

- □ Each tuple is 40 bytes long, 100 tuples per page, 1000 pages.
- □ Sailors:
  - □ Each tuple is 50 bytes long, 80 tuples per page, 500 pages.

#### Equality Joins With One Join Column

SELECT \*
FROM Reserves R1, Sailors S1
WHERE R1.sid=S1.sid

4

- □ In algebra: R ⋈ S. Common! Must be carefully optimized. R X S is large; so, R X S followed by a selection is inefficient.
- $\square$  Assume: M pages in R,  $p_R$  tuples per page, N pages in S,  $p_S$  tuples per page.
  - ☐ In our examples, R is Reserves and S is Sailors.
- □ We will consider more complex join conditions later.
- □ Cost metric: # of I/Os. We will ignore output costs.

11/16/11

### Simple Nested Loops Join

5

foreach tuple r in R do foreach tuple s in S do if  $r_i == s_i$  then add  $\langle r, s \rangle$  to result

- ☐ For each tuple in the *outer* relation R, we scan the entire *inner* relation S.
  - $\bigcirc$  Cost: M +  $p_R * M * N = 1000 + 100*1000*500 I/Os.$
- □ Page-oriented Nested Loops join: For each page of R, get each page of S, and write out matching pairs of tuples <r, s>, where r is in R-page and S is in S-page.
  - $\bigcirc$  Cost: M + M\*N = 1000 + 1000\*500
  - □ If smaller relation (S) is outer, cost = 500 + 500\*1000

## Examples of Index Nested Loops

- ☐ Hash-index (Alt. 2) on sid of Sailors (as inner):
  - □ Scan Reserves: 1000 page I/Os, 100\*1000 tuples.
  - □ For each Reserves tuple: I.2 I/Os to get data entry in index, plus I I/O to get (the exactly one) matching Sailors tuple. Total: 220,000 I/Os.
- ☐ Hash-index (Alt. 2) on sid of Reserves (as inner):
  - □ Scan Sailors: 500 page I/Os, 80\*500 tuples.
  - □ For each Sailors tuple: 1.2 I/Os to find index page with data entries, plus cost of retrieving matching Reserves tuples.

    Assuming uniform distribution, 2.5 reservations per sailor (100,000 / 40,000). Cost of retrieving them is I or 2.5 I/Os depending on whether the index is clustered!

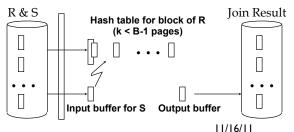

### Index Nested Loops Join

foreach tuple r in R do foreach tuple s in S where  $r_i == s_j$  do add  $< r_r$ , s > to result

- □ If there is an index on the join column of one relation (say S), can make it the inner and exploit the index.
  - □ Cost:  $M + ((M*p_R) * cost of finding matching S tuples)$
- ☐ For each R tuple, cost of probing S index is about 1.2 for hash index, 2-4 for B+ tree. Cost of then finding S tuples (assuming Alt. (2) or (3) for data entries) depends on clustering.
  - □ Clustered index: I I/O (typical), unclustered: upto I I/O per matching S tuple.

# Block Nested Loops Join

- ☐ Use one page as an input buffer for scanning the inner S, one page as the output buffer, and use all remaining pages to hold ``block" of outer R.
  - $\Box$  For each matching tuple r in R-block, s in S-page, add <r. s> to result. Then read next R-block, scan S, etc.

### **Examples of Block Nested Loops**

- □ Cost: Scan of outer + #outer blocks \* scan of inner
  - □ #outer blocks = [# of pages of outer / blocksize]
- □ With Reserves (R) as outer, and 100 pages of R:
  - □ Cost of scanning R is 1000 I/Os; a total of 10 blocks.
  - □ Per block of R, we scan Sailors (S); 10\*500 I/Os.
  - ☐ If space for just 90 pages of R, we would scan S 12 times.
- □ With 100-page block of Sailors as outer:
  - □ Cost of scanning S is 500 I/Os; a total of 5 blocks.
  - □ Per block of S, we scan Reserves; 5\*1000 I/Os.
- □ With <u>sequential reads</u> considered, analysis changes: may be best to divide buffers evenly between Runduls.

# Sort-Merge Join $(R \bowtie_{i=1}^{k} S)$

10

- □ Sort R and S on the join column, then scan them to do a `merge" (on join col.), and output result tuples.
  - □ Advance scan of R until current R-tuple >= current S tuple, then advance scan of S until current S-tuple >= current R tuple; do this until current R tuple = current S tuple.
  - □ At this point, all R tuples with same value in Ri (current R group) and all S tuples with same value in Sj (current S group) match; output <r, s> for all pairs of such tuples.
- □ R is scanned once; each S group is scanned once per matching R tuple. (Multiple scans of an S group are likely to find needed pages in buffer.)

## Example of Sort-Merge Join

''				sid	bid	day	rname
sid	sname	rating	age	28	103	12/4/96	guppy
22	dustin	7	45.0	28	103	11/3/96	
28	yuppy	9	35.0				yuppy
31	lubber	8	55.5	31	101	10/10/96	dustin
44	guppy	5	35.0	31	102	10/12/96	lubber
58	rusty	10	35.0	31	101	10/11/96	lubber
	Tubly	10	33.0	58	103	11/12/96	dustin

 $\square$  Cost: M log M + N log N + (M+N)

..

- ☐ The cost of scanning, M+N, could be M\*N (very unlikely!)
- □ With 35, 100 or 300 buffer pages, both Reserves and Sailors can be sorted in 2 passes; total join cost: 7500 (BNL cost: 2500 to 145000 1/Os)

# Refinement of Sort-Merge Join

- □ We can combine the merging phases in the sorting of R and S with the merging required for the join.
  - ☑ With B >  $\sqrt{L}$ , where L is the size of the larger relation, using the sorting refinement that produces runs of length 2B in Pass 0, #runs of each relation is < B/2.
  - □ Allocate I page per run of each relation, and `merge' while checking the join condition.
  - □ Cost: read+write each relation in Pass 0 + read each relation in (only) merging pass (+ writing of result tuples).
- □ In practice, cost of sort-merge join, like the cost of external sorting, is *linear*.

### Observations on Hash-Join

14

- □ #partitions k < B-I (why?), and B-2 > size of largest partition to be held in memory. Assuming uniformly sized partitions, and maximizing k, we get:
  - $\Box$  k= B-1, and M/(B-1) < B-2, i.e., B must be >  $\sqrt{M}$
- ☐ If we build an in-memory hash table to speed up the matching of tuples, a little more memory is needed.
- ☐ If the hash function does not partition uniformly, one or more R partitions may not fit in memory. Can apply hash-join technique recursively to do the join of this R-partition with corresponding S-partition.

11/16/11

## Cost of Hash-Join

15

- □ In partitioning phase, read+write both relns; 2(M+N). In matching phase, read both relns; M+N I/Os.
- $\Box$  In our running example, this is a total of 4500 I/Os.
- □ Sort-Merge Join vs. Hash Join:
  - ⊡ Given a minimum amount of memory (what is this, for each?)
    both have a cost of 3(M+N) I/Os. Hash Join superior on this
    count if relation sizes differ greatly. Also, Hash Join shown to
    be highly parallelizable.
  - □ Sort-Merge less sensitive to data skew; result is sorted.

UOFT: DB GROUP

11/16/11

□ Equalities over several attributes (e.g., R.sid=S.sid AND R.rname=S.sname):

General Join Conditions

- □ For Index NL, build index on <sid, sname> (if S is inner); or use existing indexes on sid or sname.
- □ For Sort-Merge and Hash Join, sort/partition on combination of the two join columns.
- □ Inequality conditions (e.g., R.rname < S.sname):
  - ☐ For Index NL, need (clustered!) B+ tree index.
  - □ Hash Join, Sort Merge Join not applicable.
  - □ Block NL quite likely to be the best join mathod here.
